

Recycled aggregates –some greenhouse issues

Jencie McRobert

Outline

- Resourceco case study – recycling aggregates in Adelaide
 - Zero Waste SA initiative
- Some roadworks applications - reducing energy use and greenhouse gas emissions
- Conclusions

Resourceco case study

Study aimed to develop a method and collect data on:

- Energy use, greenhouse gas emissions and other enviro/social impacts of Resourceco's recycling operations
 - Beneficial reuse options for recycled materials
- # Crushing plant at Resourceco ~ 45 to 50,000 tonnes road base per month (90,000 in Nov'08)

C&D WASTE STREAM - CRUSHING PLANT

1 tonne Concrete & Demolition Waste

Collection & recycling

Versus

Collection & landfill

97.0% brick rubble and concrete
1.5% steel scrap
1% combustibles (e.g timber)
- negligible residual waste

End of life
- final disposal

Comprising:

Brick rubble and concrete - crushed and screened aggregate, graded & stockpiled into products

Scrap steel - separated by magnet and mechanically deposited into steel bins and sold as scrap for export

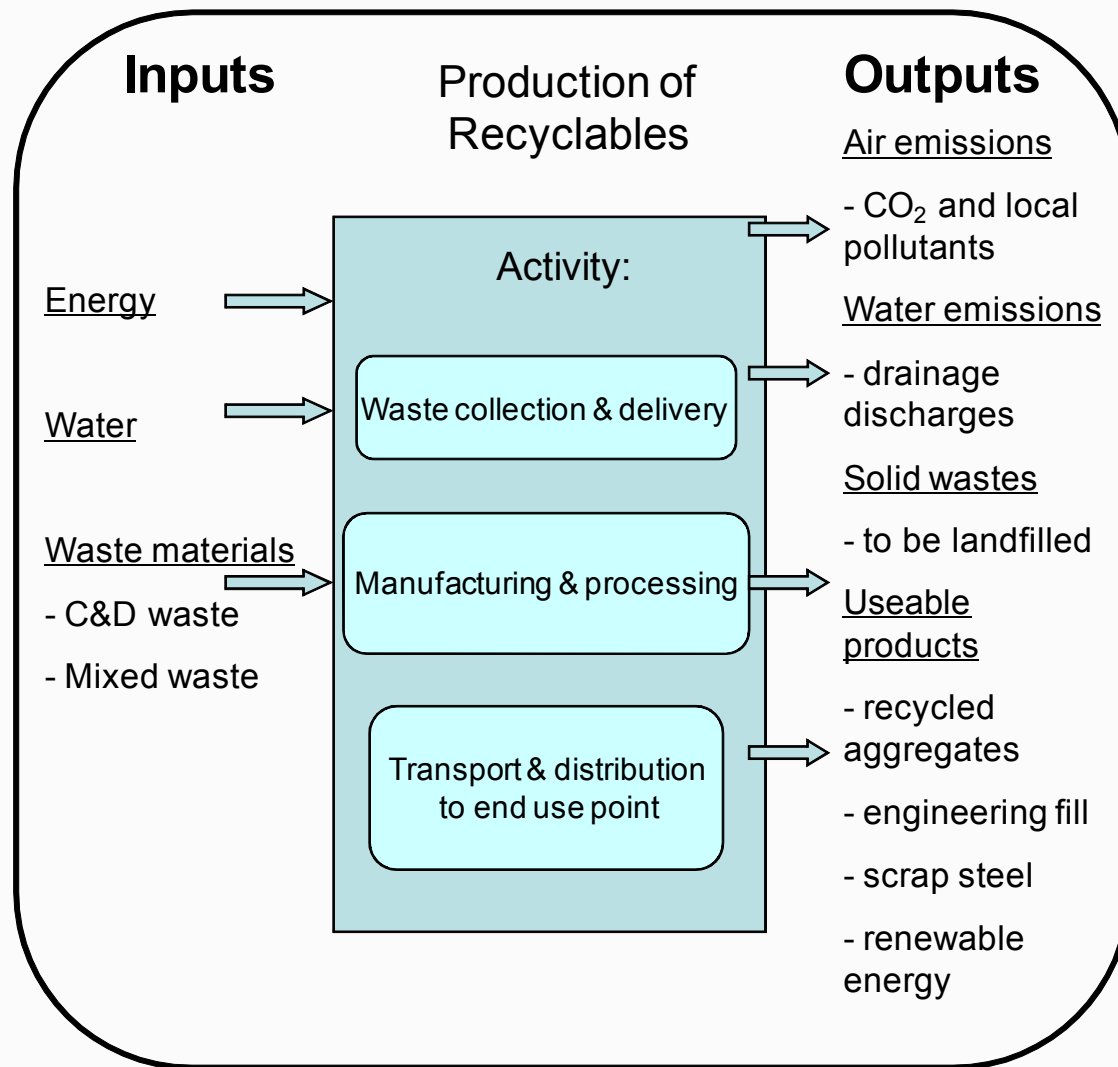

Combustibles - separated and transported to mixed waste-to-energy plant: suitable material is reprocessed in alternative fuels plant

Ground/screened product is transported to ABC receiving facility - incineration & energy recovery: producing negligible bottom ash

Residual ash
- reused in cement clinker

** From every tonne of waste delivered to Resourceco

- there are recyclables extracted and through reprocessing, there are a range of recycled products produced

Overall impact assessment:

Recycling C&D and mixed waste versus landfill :

- greenhouse emissions, toxicity, pollution (air, water), biodiversity, social (noise, dust, aesthetics, severance, odours)

Comparison: CO_{2-e} emissions

Total CO_{2-e} per unit of production (preliminary)

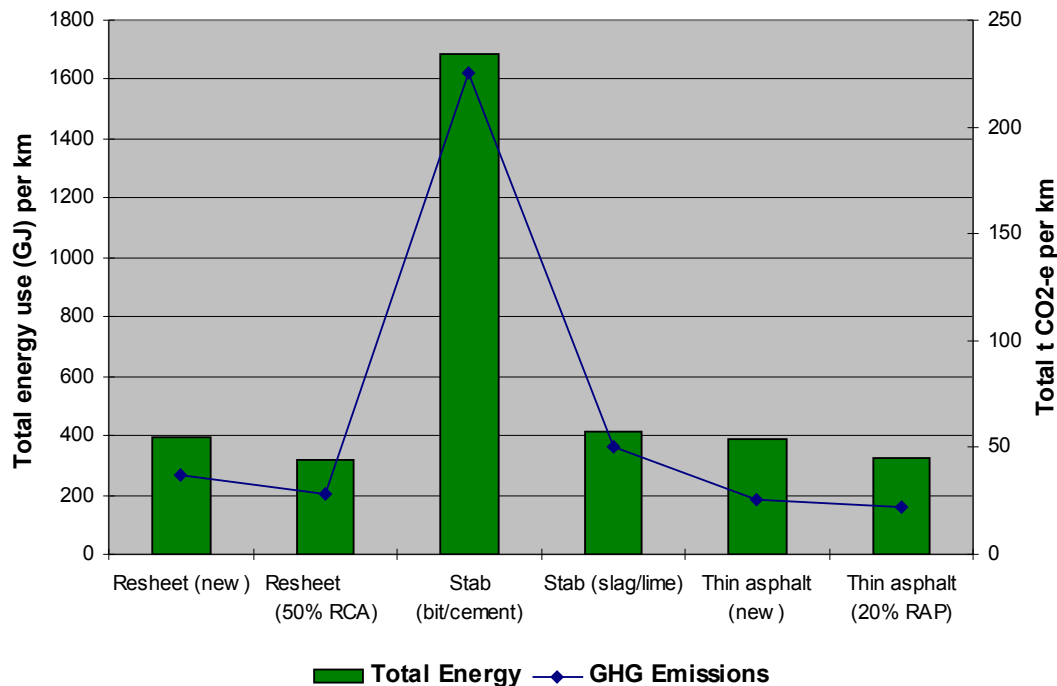

- Resourceco study – 3 kg CO_{2-e}/tonne (21 MJ/t)
 - Victorian quarry study – 7.5 kg CO_{2-e}/tonne (31 MJ/t)
-
- Process energy use and emissions of recycled aggs could represent up to 60% fewer emissions - equivalent quarry product
 - USA (2003 EPA study) - 30% less emissions for recycled aggs
 - UK (2008 Quarry Products Assoc) - 6kg CO_{2-e}/tonne overall
- & 4 kg/tonne for crushed rock - recycled ?

Comparison: CO_{2-e} emissions

Difficulties in comparing studies:

- need to know what's behind published figures
- emission factors will vary according to methodology (scope-direct/indirect) and local electricity generation (gas or coal fired, nuclear ...)

Roadworks application – cement substitutes & recycled aggregates

ARRB study for RTA (2005):

- Aim – reduce emissions in road construction & maintenance

Maintenance treatments:

- Recycled aggregates use in resheeting: RAP & RCA
- Cement substitutes in stabilisation: slag & fly ash

Cement substitution can reduce emissions by 70%

Recycled aggregates substitution - by 25 - 40%

Environmental gains - recycled aggregates

- Reduced resource consumption
- Diversion of waste materials from landfill
- Lower embodied energies and emissions (more work)
- Reduced transport emissions when reused in close proximity to reprocessing site
 - e.g. in a 10,000 tonne road construction project (~ 1 km length) there is approx. 1 tonne CO_{2-e} emissions produced per km travelled to site

Conclusions

This study has begun to collect some of the required data and develop a suitable framework.

There is a need for further local studies investigating local applications:

- Quarrying and aggregates recycling – energy assessments to generate some indicative benchmark figures
- Roadworks & general construction and maintenance case studies

Conclusions

“Carbon neutral” road construction
- industry, individual business or agency level

There are limits to the carbon neutral claim

In choosing a carbon neutral path, there is a recognised carbon neutral hierarchy:

- **Reduce:** most cost effective but requires practice change
- **Renew:** purchase of renewable energy
- **Offset:** usually cheapest but its value is questionable
